Independent Events

Compound probability is the likelihood of several events happening at once or one after the other. Compound probability is found by *multiplying* the probabilities of individual events.

Compound events can be independent or dependent. Two events are independent when one event doesn't impact the other one. Examples of independent events are flipping a coin more than once or rolling more than one die at a time.

Example

Hide

If you roll two dice, what is the probability of rolling two 6s?

Step 1
Find the probability of the first event.

The probability of rolling a 6 on one of the dice is $\frac{1}{6}$.

Step 2
Find the probability of the second event.

The probability of rolling a 6 on the other die is also $\frac{1}{6}$.

Step 3
Multiply the probabilities.

$$\frac{1}{6} \times \frac{1}{6} = \frac{1}{36}$$

The probability of getting two 6s is $\frac{1}{36}$, or **1 out of 36**.
