Value Problems

A value problem is one where the counted objects have a value. You need to consider the total number of objects and the amount they are worth.

Example 1[Hide](#)

Brad has 20 coins in his pocket, all either quarters or dimes. If he has exactly \$2.90, how many of the coins are quarters?

Step 1

Use a chart.

Let x represent the number of dimes.

If there are x dimes, there must be $20 - x$ quarters.

Now complete the value column. Multiply the number by the value for that coin. Dimes are worth \$0.10 each. Quarters are worth \$0.25 each.

	Number	Value
Dimes	x	$0.1x$
Quarters	$20 - x$	$0.25(20 - x)$

Step 2

Write and solve an equation.

$$0.1x + 0.25(20 - x) = 2.90$$

Use the distributive property.

$$0.1x + 5 - 0.25x = 2.90$$

Combine like terms.

$$5 - 0.15x = 2.90$$

Use inverse operations to isolate the variable.

$$\begin{aligned} -0.15x &= -2.10 \\ x &= 14 \end{aligned}$$

There are 14 dimes.

Step 3

Answer the question. How many of the coins are quarters? $20 - 14 = 6$ quarters

Not all value problems are about money. As you read the next example, ask yourself, "How can I tell this is a value problem?"

Value Problems

Step 1
Use a chart.
Let x represent the number of small tables.
There must be $30 - x$ large tables.
In the value column, multiply the number by how many chairs are at a table of that size.

Tables	Number	Value
Small	x	$2x$
Large	$30 - x$	$5(30 - x)$

Step 2
Write and solve an equation.
 $2x + 5(30 - x) = 117$
 $2x + 150 - 5x = 117$
 $-3x = -33$
 $x = 11$

Step 3
Answer the question. There are **11 small tables**.
