Using the Slope Formula

This formula from the GED math formula sheet uses subtraction to find slope.

slope (m) = $\frac{y_2 - y_1}{x_2 - x_1}$, where (x_1, y_1) and (x_2, y_2) are two points on the coordinate plane

Example

Hide

What is the slope of the line that passes through the points (1, 1) and (−2, 3)?

Step 1
Decide which point will be (x_1, y_1) .
Let (1, 1) be (x_1, y_1) and (−2, 3) be (x_2, y_2) .

Step 2
Substitute these values into the formula and simplify.

$$m = \frac{y_2 - y_1}{x_2 - x_1} = \frac{3 - 1}{-2 - 1} = \frac{2}{-3} = -\frac{2}{3}$$

The slope is $-\frac{2}{3}$.

There are two kinds of lines with special slopes.

Look at line l . It doesn’t rise at all. For every unit of run, the line rises 0 units. The slope is $\frac{0}{1}$, or 0.

Look at line m . It only rises; it never runs. For every unit of rise, the line runs 0 units. You could write the slope as $\frac{1}{0}$, but division by 0 has no meaning in math. The slope of a vertical line is **undefined**.
